

Project 2: Enterprise System Integrity, Schema Validation, & Change Control Protocol

 **Portfolio Methodology Note:** This project profile represents a real-world enterprise database migration that I directly orchestrated as a Co-Project Lead. Backed by my PMP® and PMI-ACP® credentials, I directed the project delivery framework, managed the customer relationship lifecycle, and authored the governance safeguards. While the backend technical scripts and schema configurations were executed by the Core Systems Engineering division, this document demonstrates my hands-on authority to analyze, map, and enforce strict Change Control and Information System Integrity benchmarks through a professional GRC lens.

Executive Case Overview

- **Domain:** Change Management, Data Integrity, Release Governance, Third-Party API Assurance
- **Target Framework Benchmarks:** NIST SP 800-53 Rev. 5 (CM-3: Configuration Change Control, SI-7: Information System Integrity, CM-8: Information System Component Inventory)
- **Objective:** Direct the end-to-end technical operational response and recovery framework for a high-consequence enterprise database migration transferring 140++ active federal endpoints from direct vendor billing to a strategic partner's reseller account architecture.

The Technical & Compliance Blockers

When a major government partner expanded its Managed Service platform, over 140+ active, in-field telematics assets required immediate database realignment. The primary objective was to establish the partner's central database as the primary system while maintaining shared access for agency-owned environments. During execution, the project faced critical blockers:

1. **Active Asset Hardware Locks:** Live-billed field hardware locked automatically against standard re-ordering protocols, causing instant transaction cancellations.
 2. **E-Commerce Workflow Defaults:** Unmapped checkout system bugs auto-selected unauthorized priority freight defaults, violating established government procurement rules.
-

GRC Execution & Control Mapping

1. Configuration Change Control (NIST SP 800-53: CM-3)

- **The GRC Approach:** Maintaining the integrity of technical change controls requires an ironclad governance presence to enforce established protocols and preserve system baselines amid stakeholder churn and organizational volatility.
 - **The Execution:** I served as the primary anchor for project continuity and protocol enforcement throughout the migration lifecycle. While I participated in the collaborative joint planning and directly executed the virtual order procurement, my core impact was driving strict framework alignment across matrixed teams. As internal and external stakeholders exited the project, I systematically held cross-functional engineering teams accountable to the five-step technical database sequencing protocol: **Virtual Order Creation** → **Database Deactivation (Via Script)** → **Serial Number Staging** → **Database Reconciliation (Via Script)** → **Shipment Finalization**, ensuring all tasks executed in strict alignment with public sector data constraints and timeline mandates. This protocol allowed the engineering team to deactivate and reconcile system configurations cleanly without interrupting active user billing profiles.
-

Quantifiable Business Outcomes & Value

- **Critical ARR Protected:** Successfully transferred 140+ active federal devices, protecting a high-value, five-figure annualized subscription portfolio on a single execution loop.
 - **Data Continuity:** Achieved the migration with zero data loss, and zero service loss.
 - **Repeatable Enterprise Model:** Authored a five-point Lessons Learned Register and standard operating playbook, adopted by senior management as the enterprise standard for future federal account onboarding.
